

## **SECTION 4 - WATER QUALITY**

### **Section 4.1 WATER QUALITY ASSESSMENTS:**

All waters in New York State are assigned a letter classification that denotes their “best uses.” In brief, the classifications are as follows:

- Class A Drinking water (and all other uses below).
- Class B Swimming and boating (and all other uses below).
- Class C Fishing and fish propagation. Possibly swimming and boating, but may be limited.
- Class D Fishing, but not fish propagation. Possibly swimming and boating, but may be limited.

An additional designation of T indicates that the river supports trout survival. If a river also supports trout propagation, TS is added.

There are specific numeric and narrative standards that apply to the different classifications. For example, the pH of A, B, and C waters must be between 6.5 and 8.5. The dissolved oxygen concentration for A, B and C trout spawning waters (TS) cannot be less than 7.0 mg/L from other than natural conditions. Except for Class A waters, nutrients (nitrogen and phosphorus) are regulated only by a narrative standard: “None in amounts that will result in growths of algae, weeds and slimes that will impair the waters for their best usages.”

For more information on stream classifications and standards, see: *NY State Codes, Rules and Regulations Title 6, Chapter X: Part 701: Classifications-Surface Waters and Groundwaters*<sup>1</sup> and *Part 703: Surface Water & Groundwater Quality Standard*<sup>2</sup>:

The classification of the Lower Non-tidal Rondout Creek is as follows:

From the Eddyville Dam to Kerhonkson	Class B
From Kerhonkson to the mouth of the Vernooy Kill	Class B(T)
From Vernooy Kill to Sandburg Creek	Class C(T)
From Sandburg Creek to Honk Lake	Class C
From Honk Lake to the Rondout Reservoir dam	Class C(TS)

Many of the tributaries to the Lower Non-Tidal Rondout are designated trout and/or trout spawning waters, and a few are Class A drinking water streams (in addition to tributaries to the Rondout Reservoir).

For more information on classifications in the Rondout Creek Watershed, see: *NY State Codes, Rules and Regulations Title 6, Chapter X, Part 855: Rondout River, Rondout Creek and Wallkill River Drainage Basin*<sup>3</sup>

## **WATER QUALITY ASSESSMENTS – BACKGROUND AND METHODS**

Background: The NYSDEC Division of Water, Bureau of Water Assessment and Management, is responsible for monitoring New York State waters to determine overall quality of waters, trends in water quality, and to identify water quality problems and issues. This monitoring effort is coordinated through the Rotating Integrated Basin Studies (RIBS) Program. RIBS monitoring produces 2 years of data on each of the state's 17 major drainage basins in a 5-year cycle. In year one of the sampling effort, screening sampling is conducted on a large number of waterbodies; in year two, a smaller number of locations are intensively sampled. In the screening year, only habitat assessments and macroinvertebrate sampling are conducted; in the intensive year, water chemistry, bottom sediment and invertebrate tissue chemistry, toxicity testing, macroinvertebrate assessments, and habitat assessment are done.

In 2002, the NYSDEC completed an extensive Biological Assessment of the Rondout Creek Watershed. In the next (most recent) 5-year cycle for the Rondout (2007-2008), the NYSDEC was only able to assess a few sites in the Rondout Creek Watershed because of the large area that the state must cover each year. In 2007, they sampled one site on the Rondout Creek and one site on each of two major tributaries, Sandburg Creek in the Village of Ellenville and Mill Brook in the Town of Rochester. No intensive sites were located on the Rondout in 2008, but one location in Kerhonkson at State Route 44/55 was sampled as part of a special study on nutrients.

**Photo 4.1.1 Looking upstream from sampling site Tan House Brook, Snyder Estate, Rosendale.**

Recognizing the need for more water quality data on a smaller scale, the NYSDEC Hudson River Estuary Program (HREP) provided funding to Hudson Basin River Watch (HBRW) in 2007 to assess 15 sites in the Rondout Creek Watershed. HBRW selected sites based on input from the Rondout Creek Watershed Council (RCWC), the New York State Department of Environmental Conservation (NYSDEC), and the New York City Department of Environmental Protection (NYCDEP). Sites that were selected included those sites that had never been studied by the NYSDEC or NYCDEP, sites on some of the smaller tributaries, and those that had been identified as potential areas of concern in the 2002 assessment completed by the NYSDEC. Two of the 15 sites were located above the Rondout Reservoir; their results are not discussed in this watershed management plan, as they likely do not significantly impact the water quality of the Lower Rondout Creek.

In 2009 and 2010, the Rondout Creek Watershed Council contracted with HBRW to assess two additional sites each year on the Sandburg Creek to try to determine the location of impacts on this major tributary to the Rondout.

Methods: The assessments mentioned above were “Biological Assessments” using NYSDEC Stream Biomonitoring Unit methods (used both by NYSDEC and HBRW). The primary indicators of water quality in these assessments are freshwater benthic macroinvertebrates

(BMIs). BMIs are larger-than-microscopic invertebrate animals that live in and on stream bottoms, including aquatic insects, worms, clams, snails, and crustaceans. BMIs are useful water quality indicators because different species have different sensitivities to environmental impacts. They are less mobile than fish, and thus cannot avoid discharges or other pollution. Unlike chemical indicators, BMIs provide a picture of overall, integrated water quality, including synergistic effects; substances lower than detectable limits, and non-chemical impacts to the habitat, such as siltation or thermal changes.

Live BMI samples are collected in riffle habitats using a kick net, then preserved and identified in a laboratory under a microscope. The results are used to calculate four different “metrics” that are then averaged to find an overall water quality score for each site. Calculation of the metrics is based on the types and number of organisms present and known tolerances of different organisms to various amounts and types of pollutants. The overall water quality score is called a “Biological Assessment Profile” (BAP) and is ranked on a scale from 0 to 10, with 10 indicating the best water quality. The BAP can fall into one of four categories of pollution impact, with each category corresponding to a specific quarter of the scale: “severely impacted” = 0-2.5, “moderately impacted” = 2.5-5.0, “slightly impacted” = 5.0-7.5, and “non-impacted” = 7.5-10.

The results are also used to generate an “Impact Source Determination” (ISD) for each site. The NYSDEC Stream Biomonitoring Unit uses a method called “Impact Source Determination” (ISD) to identify types of impacts that may negatively affect water quality. The BMI community at a site is compared to existing models of known communities indicative of certain types of

Table 1. Descriptions of Impact Source Determination (ISD) classes used by New York State Department of Environmental Conservation for stream biomonitoring.

ISD Class	Description
Natural	Minimal human impacts. Includes pristine stream segments and those receiving discharges that minimally affect the biota.
Nonpoint nutrients	Mostly nonpoint agricultural and sources with similar impacts. Includes row crop runoff, golf course runoff, well-treated sewage effluent, and urban runoff. May include pesticide effects.
Toxic	Industrial, municipal, or urban runoff. May include municipal waste-water treatment plant discharges that include industrial wastes, and (or) are characterized by high ammonia or chlorine levels.
Organic	Sewage effluent and (or) animal wastes. Includes conventional waste-water treatment plant discharges, livestock waste inputs, and failing septic systems.
Complex	Municipal and (or) industrial. Includes industrial point sources and municipal waste-water treatment plant discharges that include industrial wastes. May also include combined sewer overflows and urban runoff.
Siltation	Sites affected by moderate to heavy deposition of fine particles.
Impoundment	Includes upstream lake or reservoir releases, dammed stream segments, or stream segments with upstream areas of natural pond, wetland, or sluggish zones.

impacts. If no model exhibits at least a 50% similarity to the sampled community, then the ISD results are inconclusive. Table 4.1.1 lists the seven ISD models (“classes”) used by the NYSDEC<sup>4</sup>.

For more information about the NYSDEC Stream Biomonitoring Unit methods, visit <http://www.dec.ny.gov/chemical/23847.html>

Other basic physical and chemical parameters are also assessed at each site. Physical parameters include depth, width, current velocity, percent canopy cover, percent embeddedness, percent of different substrate sizes, aquatic vegetation present, and habitat quality. Chemical parameters include dissolved oxygen, pH, conductivity, and temperature. These are measured with a calibrated digital “Hydrolab Quanta Water Quality Monitoring System.”

## WATER QUALITY ASSESSMENTS - FINDINGS

Mainstem Rondout: The Lower Non-Tidal Rondout Creek maintains fairly good water quality, but numerous point and non-point sources of pollution in the watershed may threaten the health of the river, as many areas are showing slight signs of human impact.

The 2007 assessment by HBRW, combined with data from the NYSDEC, found the water quality to be “non-impacted” below the Rondout Reservoir at Lackawack, but “slightly impacted” at the Eastern Correctional Facility (both sites in the Town of Wawarsing). The water quality continued to be “slightly impacted” at several sites downstream in the towns of Wawarsing and Rochester (Port Ben Road in East Wawarsing, two sites in Kerhonkson, a site in Accord, and the Alligerville Bridge).

The 2007 assessment by HBRW, combined with data from the NYSDEC, found the water quality to be “non-impacted” below the Rondout Reservoir at Lackawack, but “slightly impacted” at the Eastern Correctional Facility (both sites in the Town of Wawarsing). The water quality continued to be “slightly impacted” at several sites downstream in the towns of Wawarsing and Rochester (Port Ben Road in East Wawarsing, two sites in Kerhonkson, a site in Accord, and the Alligerville Bridge). The water quality did not recover to “non-impacted” until the town of Rosendale, at the County Route 7 bridge, but then dropped back down to “slightly impacted” after the State Route 32 bridge in Rosendale, downstream of the Rosendale Wastewater Treatment Plant (WWTP). The river then became “moderately impacted” further downstream, below the confluence with the Wallkill River and the large hydroelectric dam at Sturgeon Pool.

Photo 4.1.2 HBRW Stream Monitoring Training on Rondout Creek in Kerhonkson. (Photo: M. Cheo)

<sup>4</sup> Riva-Murray, K., et. al., 2002. Impact Source Determination with Biomonitoring Data in New York State. *Northeastern Naturalist*, 9(2):127-162.

The 2002 NYSDEC assessment showed trends similar to the 2007 HBRW assessment, with sites in Wawarsing found to be “slightly impacted,” although the recovery to “non-impacted” occurred much earlier, in Accord (Town of Rochester). The 2002 assessment did not sample downstream of Rosendale.<sup>5</sup>

The most recent data on the Rondout is from 2008 when the NYSDEC sampled just one site, which showed that the Rondout was still “slightly impacted” at the 44/55 bridge in Kerhonkson (Town of Wawarsing)<sup>6</sup>.

These water quality assessments were based on analyzing samples of the stream invertebrate community (“Biological Assessments”). Note that no surveys of the Rondout Creek were undertaken in the Town of Marbletown because this methodology cannot be used in areas close to large impoundments.

Tributaries: Most tributaries were found to be “non-impacted” in both 2002 and 2007. A few tributaries, including Peters Kill, Kripplebush Creek, and Saunders/Stony Kill were found to be “slightly impacted,” but due to natural habitat or weather conditions rather than human impact. The Mill Brook was found to be “slightly impacted” in 2002 but “non-impacted” in 2007.

The main tributary that requires further investigation is Sandburg Creek, a major tributary that flows through the Village of Ellenville before entering the Rondout south of Napanoch. In both 2002 and 2007, the Rondout dropped by one water quality category (from “non-impacted” to “slightly impacted”) between the sites upstream and downstream of where the Sandburg flows into the Rondout.

The Sandburg Creek flows east through rural Sullivan County to the Hamlet of Spring Glen in Wawarsing. It then turns north, flowing through the old Nevele Grande Resort site and the currently operating Honors Haven Resort. It then flows through the Village of Ellenville. On the outskirts of the village, the Sandburg receives discharge from the Ellenville WWTP. Shortly thereafter it is met by the “non-impacted” Beer Kill, and then the Rondout.

In 2002, the Sandburg Creek was “non-impacted” at Canal Street in the Village of Ellenville. In 2007, it was “slightly impacted” at Canal Street and also just downstream of the Ellenville WWTP. In 2009, HBRW assessed the creek at two sites upstream of Ellenville, in the Hamlet of Spring Glen and at the Honors Haven Resort golf course. Both sites were found to be “non-impacted.” In 2010, the Sandburg was “slightly impacted” (but close to “non-impacted”) at a site just downstream from the Honors Haven Resort golf course and “non-impacted” at Canal Street in the Village of Ellenville.

More information is needed to flush out the condition of the Sandburg Creek and its impact on the Rondout. In 2007, flow conditions were fairly low, so the BMI community may have been

<sup>6</sup> Alexander J. Smith, NYSDEC Stream Biomonitoring Unit, email correspondence, October 2010

more vulnerable to the various runoff and discharge influences than in 2010, when flow conditions were higher. However, without having multiple samples from each site in each year, it is difficult to determine whether the different results reflect true water quality changes or natural variation inherent in the biological community and sampling methodology.

Unfortunately there is no data for 2010 on the status of the Rondout downstream of the Sandburg. It would be interesting to know if the Rondout was still “slightly impacted” downstream of the Sandburg even though the Sandburg at Canal Street was “non-impacted” in 2010. In 2002, this was the case: the Sandburg at Canal Street was “non-impacted” and the Rondout in East Wawarsing was “slightly impacted.” Impacts that year could have come from urban runoff from the Hamlet of Napanoch and/or from the Napanoch WWTP. Not enough sites were sampled to tease out these possible impacts.

Tables 4.2 and 4.3 list all sampling sites from 2002 to 2010, their locations, BAP scores, ISD classes (where available), and stream classifications. For more detailed information on the water quality assessments at each site sampled by HBRW, see Appendix J.

Site #	Town, Village, or Hamlet	Location	Year, BAP, Assessment, ISD	Classification
RN03 & DEC	Lackawack	Sportsmen Rd	2002: Non-impacted, Natural 2007: 7.91, Non-impacted, NPS nutrients & Natural	C(TS)

**TABLE 4.3: Biological Assessment Profile (BAP) Scores, Water Quality Assessments, and ISD Results, By Year Sampled for Tributaries to the Rondout Creek (listed from upstream to downstream).** Note: Site #'s are listed for HBRW sites. Site #'s are not available for DEC sites. In some cases, DEC and HBRW used the same sites. Not all information is available for all sites. Additional information from DEC sites can be obtained from the NYSDEC Bio-monitoring Unit. Additional information from other sites can be obtained from HBRW.

Water Quality Standards: None of the sites assessed by HBRW violated the pH or dissolved oxygen standards for their classification. However, when a river is “moderately” or “severely” impacted based on a biological assessment, it is likely that the river is no longer meeting its uses. The site on Creeklocks Road downstream of the confluence with the Wallkill was “moderately impacted.” This section of the river is class B, which includes swimming, boating, fishing and fish propagation. A “moderately impacted” river may not be able to support these uses.

The Creeklocks Road site was the only “moderately impacted” site. But a majority of sites scored as “slightly impacted.” Thus while much of the river may still be supporting its uses, it is no longer in a completely natural state, and the aquatic community is experiencing some stress from human impacts.

It is also important to note that the assessments did not include bacteriological sampling, so it is not known if the river is meeting its standard for coliform bacteria. This is an important indicator of health for a Class B (swimming) river.

## POTENTIAL SOURCES OF IMPACTS

Non-point Source Pollution: “Non-point nutrients” was by far the most common source of impact indicated by the ISD. This ISD class refers mainly to inputs of nitrogen and phosphorus, which can cause excess algal growth, depressed oxygen conditions, and negative impacts to the aquatic community. In 2007, the ISD indicated “non-point nutrients” for almost all mainstem Rondout sites except the Eastern Correctional Facility in Wawarsing. “Non-point nutrients” were also indicated for almost all the tributaries that were “slightly impacted.”

Non-point nutrients can come from a variety of sources including agricultural areas, golf courses, and urban areas. In addition these nutrients can come from “well-treated sewage effluent” which refers to effluent from septic systems or WWTPs in which the organics have been broken down but nutrient concentrations remain. There is widespread agricultural activity in the Rondout Valley, but it may be more likely that the Rondout’s drop to “slightly impacted” below the confluence with the Sandburg Creek is from urban runoff entering Sandburg Creek from the Village of Ellenville and contributions from various WWTP discharges.

Photo 4.1.3 Non-Point Sources: Salt loading

Point Source Pollution: There are several SPDES discharges in the Rondout Creek Watershed in the Town of Wawarsing, none in the towns of Rochester and Marbletown, and one in the Town of Rosendale. The 2007 assessments looked at sites upstream and downstream of four wastewater treatment plants (WWTPs): Ellenville, Napanoch, Kerhonkson, and Rosendale.

The Ellenville WWTP did not cause any significant change in the BAP score of the Sandburg Creek; the site upstream of the Ellenville WWTP (Canal Street) was already “slightly impacted.” Thus non-point urban runoff from the village or some other impact upstream may have caused the water quality impacts on the Sandburg Creek in 2007. However, wastewater effluent could have prolonged the creek’s recovery. Similarly, the Napanoch and Kerhonkson WWTPs did not cause any significant changes in the BAP score of the Rondout Creek; the sites upstream and downstream of each WWTP were all “slightly impacted.”

Fig. 4.1.4 Point Sources = End of Pipe

The discharges could have, however, been responsible for prolonging the river's recovery. The ISD classes "Organic" and "Complex" indicate that municipal WWTPs could be one source of impact, among other possible sources. In 2007, the ISD indicated "Complex" at two sites that were downstream of WWTPs: Ellenville and Kerhonkson. "Complex" also appeared at Route 44/55 in 2002 and "Complex" and "Organic" appeared at that site in 2008. "Organic" also appeared at the Alligerville Bridge in 2007.

None of the three WWTPs in the area (Ellenville, Napanoch, and Kerhonkson WWTPs) had any violations of their SPDES permit standards during any of the years in which water quality assessments occurred.<sup>7</sup>

Further downstream in Rosendale, the river had recovered to "non-impacted," but dropped to "slightly impacted" just downstream of the Rosendale WWTP. The Rosendale WWTP does on occasion violate its standard for total suspended solids, but there were no violations in the months of August and September of 2007.<sup>8</sup>

It is possible this drop is partially due to habitat differences. BMI's are found in riffles, shallow areas where the water moves quickly over rocky bottoms. Downstream of the WWTP, the riffle spanned the width of the river, but was not as long as it was wide. Ideally, a riffle should be twice as long as the width of the river. Upstream of the WWTP, the riffle met those criteria.

Impoundments and Channelization: The Rondout Reservoir dam did not exert any noticeable effect on water quality. The macroinvertebrate community at Lackawack was "non-impacted" both in 2002 and 2007.

Fig. 4.1.5 Rondout Creek immediately downstream of confluence with Walkkill below Sturgeon Pool

**Site RN15, Creeklocks Road  
September 15, 2007, 5 p.m.**

**Site RN15, Creeklocks Road  
September 16, 2007, 9 a.m.**

<sup>7</sup> Leonard M. Distel, Supervisor, Town of Wawarsing, and Mike Ryman, Chief Operator, Village of Ellenville Sewer Department, personal communications, November 2010.

<sup>8</sup> Terry Johnson, Water and Sewer Superintendent, Town of Rosendale, personal communication, October 2010.

The most impacted site in the whole watershed (found to be “moderately impacted” in the 2007 HBRW assessment) is located downstream from the confluence with the Wallkill River and is greatly affected by large changes in flow from the Central Hudson hydroelectric dam at Sturgeon Pool. Photos in Fig. 4.1.6 were taken at that site at 5 p.m. one day (shortly after a release) and 9 a.m. the following day after the high waters had subsided. The difference in flow in that 16-hour period is significant.

The old Delaware and Hudson Canal channel connects to Sandburg Creek upstream of the Village of Ellenville and the Honors Haven Resort. It did not exert any noticeable effect on water quality. The macroinvertebrate community was “non-impacted” at the Honors Haven resort in 2009 and “slightly impacted” (but close to “non-impacted”) in 2010.

## RECOMMENDATIONS

Controlling Non-point Source Nutrients: Non-point nutrients can be controlled through storm water management. The NYSDEC provides storm water management guidance to municipalities through its “Municipal Separate Storm Sewer Systems” (MS4) program<sup>9</sup>. MS4s are any system that conveys storm water, such as roads, pipes, catch basins, curbs, gutters, ditches, man-made channels, or storm drains. They can be owned or operated by a State, city, town, borough, county, parish, district or other public body that discharges into the waters of the United States. The municipal separate storm sewer is designed or used for collecting or conveying stormwater that is not a combined sewer or part of a Publicly Owned Treatment Works (POTW). Municipalities that are designated as “MS4 Communities” through the NYSDEC Phase II Stormwater Permit Program must develop, implement, and enforce a “Storm water Management Program” (SWMP) to reduce pollution to the “maximum extent practicable” (MEP) to protect water quality. SWMPs must include six “minimum control measures,” including:

1. Public Education and Outreach;
2. Public Involvement/Participation;
3. Illicit Discharge Detection and Elimination;
4. Construction Site Runoff Control;
5. Post-Construction Runoff Control; and
6. Pollution Prevention/Good Housekeeping at municipal sites and operations.

Public education and outreach is important because people value their waterways and implementing this measure will help them to understand what they can do to protect and restore the health of their waterbodies. This will also provide the basis for public

support for other control measures and projects related to the waterways. The public education and outreach program should include information about the impacts of stormwater discharges

---

<sup>9</sup> Overview of the Municipal Separate Stormwater Sewer System (MS4) Phase II Stormwater Permit Program. A Summary of MS4 Phase II Permit Requirements. Revised August 2003  
[http://www.dec.ny.gov/docs/water\\_pdf/ms4\\_overview.pdf](http://www.dec.ny.gov/docs/water_pdf/ms4_overview.pdf)

on waterbodies, pollutants and their sources, and preventative measures that can be taken to reduce their occurrence. A possible program for this might include speakers to community groups and schools, utility bill insets, displays at events or malls, and news articles or radio spots.

Public involvement and participation will help MS4s cultivate stronger programs and higher compliance levels if they involve people in the SWMP from the beginning. The public involvement must also comply with public participation and involvement provisions of the Clean Water act, as applicable. The public involvement/participation program will identify key individuals and groups who are interested in or affected by the SWMP. It will also describe the activities the MS4s will perform to provide program access and gather needed input. To ensure the public has the ability to become and remain involved the name contact person for the SWMP must be published. Also the draft annual report must be presented before submitting the annual report, at a meeting that is open to the public with time for public input. The summary of the input and comments should be included in the annual report, and the final report should be made available for public inspection. The program might include activities such as forming an advisory committee that will work in corroboration with other municipalities, and encouraging citizen volunteer programs for beach cleanups, litter removal and stream monitoring.

Illicit discharge detection and elimination will reduce the amount of discharges that enter the system through direct or indirect connections. This results in inadequately treated discharges that contribute high levels of pollutants, including toxics, heavy metals, oils and grease, viruses and bacteria that enter waterbodies. The municipalities must develop, implement, and enforce a program to detect and eliminate illicit discharges into the MS4. Another requirement is the creation of a map showing the location of any points where an MS4 discharges to either the waters of the U.S. or to another MS4, and the names and location of all waters of the U.S. The formation of an ordinance or other regulatory mechanism, that will prohibit illicit discharges into the storm sewer system and implement appropriate enforcement procedures and actions is a major regulatory aspect to detect illicit discharges. Additionally municipalities should develop and implement a program to detect and address non-stormwater discharges to the system. Public employees, businesses and the general public of hazards associated with illegal discharges will increase public awareness and involvement, will simultaneously strengthening the previous requirements. Measurable goals and appropriate management practices should be implemented to ensure the reduction of all pollutants of concern from illicit discharges to the stormwater system to the MEP. Possible programs for this measure might include conducting shoreline surveys, inspecting storm sewers, and establishing citizen watch groups.

Construction site runoff control requires measurable goals and appropriate management practices to ensure the reduction of all pollutants of concern from illicit discharges to the stormwater system to the MEP. A program to reduce pollutants in stormwater runoff to the MS4 from construction activities that disturb land of one acre or more must be developed and implemented. However, if construction is on land less than one acre, is part of a larger common plan of development or sale, it must be included in the program. The program should at a minimum provide the development and implementation of an ordinance or other regulatory mechanism to control erosion and sediment control management practices, and the implementation of sanctions to ensure compliance, if needed. Site plan review procedures that will incorporate consideration of potential water quality impacts, with pre-construction site plans to ensure consistency with

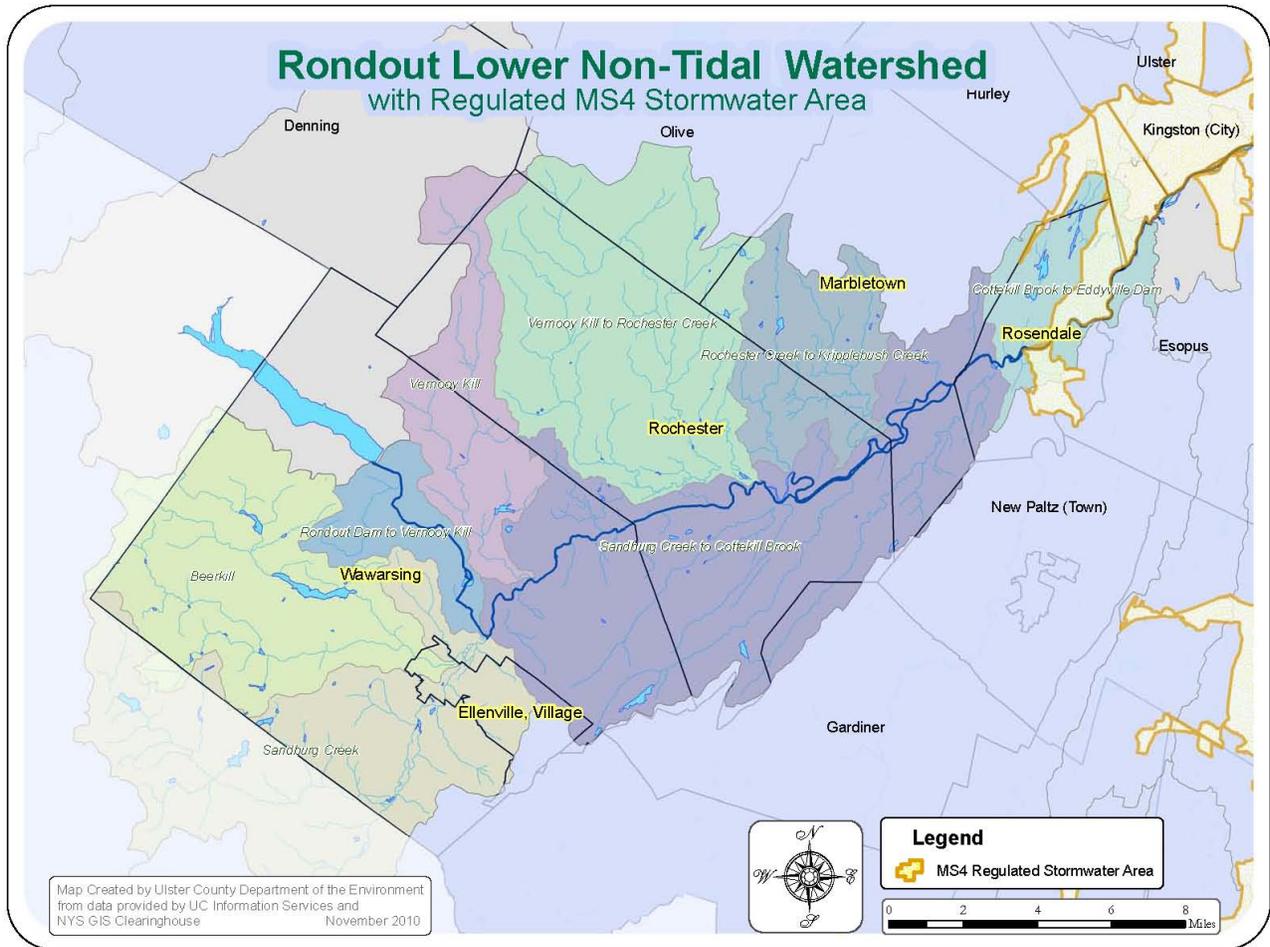

local sediment and erosion control requirements must also be included. Finally procedures for site inspections and enforcement of control measures, and education and training for construction site operators about the requirements is necessary to ensure the successfulness of construction site runoff control. MS4s need to become familiar with the SPDES General Permit for Stormwater Discharges from Construction Activity because their program must, at a minimum, provide equivalent protection to this permit.

Post construction site runoff control is important because as runoff flows over land altered by development, it picks up pollutants that are then transferred into the waterways. Prior planning and design for minimization of pollutants in post construction areas is a cost effective approach to stormwater quality management. MS4s must develop and implement a program that reduce the discharge of pollutants to the MEP, through the use of ordinances or other regulatory mechanism to address post construction runoff from development and redevelopment. As with construction site runoff control, post construction site runoff requires that there are measurable goals, management practices, and controls in place to ensure the reduction of all pollutants to the MEP. Inspection of development and redevelopment sites must be carried out to insure compliance and penalize violators. In addition to inspecting sites the use of zoning ordinances and other regulatory mechanisms must be used to successfully reduce construction runoff.

Pollution prevention and good housekeeping measures for municipal operations will reduce or prevent pollution from the operation and maintenance activities, which can become sources of pollutants that need to be minimized through the SWMP. Good housekeeping measures for municipal operations will reduce or prevent pollution from entering nearby waterbodies with stormwater runoff. MS4s must develop and implement an operation and maintenance program that will reduce and prevent the discharge of pollutants to the MEP from activities such as park and open space maintenance, roadway maintenance, adjustments to local geography to affect the continuous movement of water on, above and below the landscape. As a guideline the management practices identified in the NYS Management Practices Catalogue for Nonpoint Source Pollution Prevention should be utilized as needed. Possible program activities are the development of maintenance schedules and inspection procedures for structural and non-structural controls, and coordinate with flood control managers to identify and address environmental impacts from flood management projects.

Fig. 4.1.7: Severe erosion.

The towns of Marletown and Rosendale are the only MS4 communities in the Lower Non-Tidal Rondout Creek Watershed. They have implemented successful SWMPs. Table 4.1 outlines specific practices used by these communities. Current efforts to manage and educate about stormwater have been successful. Rosendale has found that flooding has decreased due to increased inspection and maintenance of post construction best management practices. Marletown found that stormwater trainings for contractors resulted in improved erosion and sediment control at construction sites. When economically feasible, Marletown plans to incorporate runoff reduction techniques and green infrastructure in the routine upgrade of existing stormwater conveyance systems and municipal operations.<sup>10</sup>

Table 4.1: Practices Implemented in MS4 communities in LNT Rondout Creek Watershed

<b>Practice Implemented</b>	<b>Marbletown</b>	<b>Rosendale</b>
Developed educational materials on stormwater management and related issues.	X	X
Encouraged public involvement in stream clean ups.	X	X
Encouraged public involvement in community meetings to review SWMPs.	X	X
Mapped 100% of stormwater outfalls and screened for dry weather discharges.	X	X
Hosted public presentations on Better Site Design and Low Impact Development	X	
Provided stormwater training sessions for town employees	X	
Marked stormdrains		X
Corrected illicit discharges (failing septic systems)		X
Implemented and enforced regulatory mechanisms to control illicit discharges and manage stormwater runoff from construction sites and new developments, post-construction.	X	X

Other municipalities in the watershed can follow the examples set by Marbletown and Rosendale to educate and involve the public in stormwater issues and implement practices that eliminate illicit discharges and reduce stormwater runoff and resulting non-point source pollution from construction sites, new developments, and municipal operations.

An illicit discharge is a discharge that enters a MS4 system directly or indirectly, but it is not a discharge that MS4 systems are designed to process. They could include: sanitary wastewater, septic tank effluent, car wash wastewaters, improper oil disposal, radiator flushing disposal, laundry wastewaters, spills from roadway accidents, and improper disposal of auto and household toxics. Other non-stormwater discharge flows that may not be considered “illicit discharges” but can cause non-point source pollution include water line flushing, irrigation water, foundation and footing drains, residential car washing, swimming pool discharges, street wash water, and fire fighting activities. In addition to mapping and inspecting MS4 outfalls, mapping potential sites of illicit discharges could be a helpful strategy in controlling stormwater pollution. For example, if septic systems along a river corridor were mapped, this could help identify potential hot spots of pollution and help to target future sites for stream monitoring efforts.

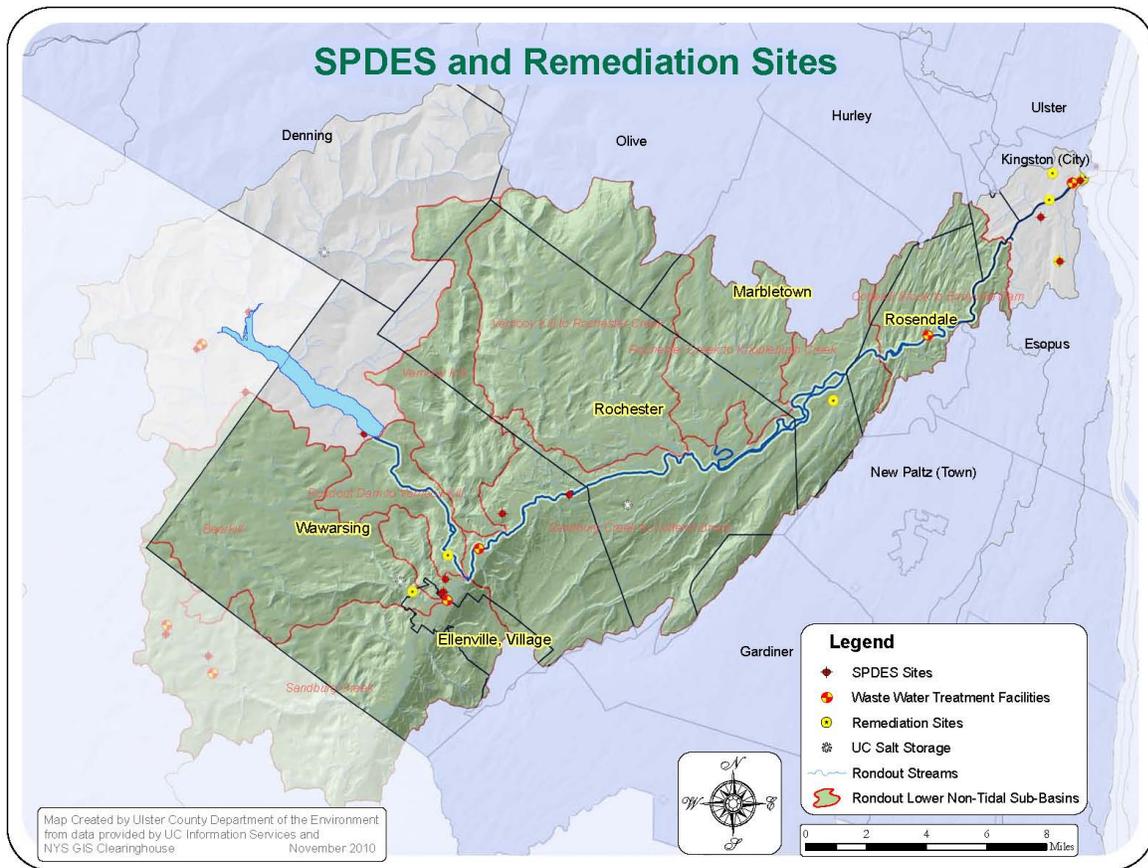

Point Source Pollution: While none of the WWTPs in Wawarsing appeared to have a significantly negative influence on the Rondout Creek based on the 2007 study, they may be prolonging the river’s recovery. It would be important to monitor the operations of these SPDES discharges for violations and continue to conduct water quality assessments upstream and downstream of their locations. Regarding the Rosendale WWTP, it would be helpful to consult with NYSDEC Biomonitoring Unit about the habitat quality in the site to help judge if it may have influenced the “slightly-impacted” water quality result.

When active all the landfills in the lower in the lower non-tidal Rondout were unlined. However, they have all been closed and replaced with transfer station, where recyclables and non-

recyclable waste are stored prior being transported to the Ulster County Resource Recovery Agency to be processed and marketed or sent to out of county landfills. Although there are currently no active landfills, the leachate or emissions from the closed landfills in each of the towns and could act as a potential source of point source pollution.<sup>11</sup>

Table 4.2: Landfill Closures in LNT Rondout Creek Watershed Municipalities

Town	Active dates	Closure dates
Wawarsing	1975-1993	1997
Marbletown	1977-1982	NA
Rochester	1973-1993	1996
Rosendale	1978-1993	1998

**Further Studies:** In addition to conducting water quality assessments up and downstream of SPDES discharges, it would be helpful to assess water quality upstream and downstream of any significant stormwater discharges that are detected, or of stormwater runoff control measures that

<sup>11</sup> Laibach, Terry; Ulster County Solid Waste Management, email communication November 2010

are implemented. This will help determine whether water quality impacts are coming from point sources or non-point sources of pollution.

The ISD indicated nutrients as the most common source of impact in the watershed. Nutrients are likely coming from many non-point sources in the watershed, so reducing stormwater runoff could reduce this source of pollution. In addition, “Well-treated sewage effluent” is another possible source of excess nutrients. WWTPs are usually required to remove organic and toxic materials from their effluent, but often not required to remove nutrients such as phosphorus. More research on this potential source of nutrients from WWTPs would be helpful.

Excess nutrient loading into a river can lead to eutrophication – a situation that can cause oxygen levels to drop below what is needed to sustain a healthy aquatic community. “Cultural” (human caused) eutrophication of surface waters has become a major source of water quality impairment throughout the US. In response, the United States Environmental Protection Agency (USEPA) has devised a national strategy for the development of regional nutrient criteria. New York State has an effort underway to revise its narrative nutrient standard.

The NYSDEC has recently developed a method of measuring stream nutrient enrichment using BMIs called the “Nutrient Biotic Index” (NBI).<sup>12</sup> The level of eutrophication in a stream can be calculated based on the tolerance of the various BMI taxa to phosphorus and nitrogen. For further exploration on the impact of nutrients in the Rondout Creek Watershed, the data discussed in this section could be analyzed using this methodology.

It would also be important to conduct an assessment of coliform bacteria on the Rondout. Each community along the river could provide input on what areas are used for swimming, and a study could be designed accordingly, using NYS Department of Health standards for coliform bacteria at bathing beaches. This assessment would be especially useful in the High Falls area, where swimming is popular and no water quality assessment has ever been conducted.

Another recommended area of further study is the Sandburg Creek and the Rondout in Wawarsing. A study that included assessments of the Lackawack, Honors Haven, Canal Street, Ellenville WWTP, Eastern Correctional, and Port Ben Road sites, plus an additional site on the Rondout upstream of Sandburg Creek but downstream of the Hamlet of Napanoch, would help determine the following:

- The level of impact in the Sandburg Creek
- Where the impact may be coming from (Honors Haven golf course, Village of Ellenville urban runoff, or Ellenville WWTP).
- The level of impact in the Rondout Creek in Napanoch and East Wawarsing.
- Where the impact may be coming from (Sandburg Creek, Napanoch area urban runoff, or the Napanoch WWTP).

There are numerous factors that affect the health of a river. With continued water quality assessment, and reduction of the human impacts found, the relatively good health of the Rondout can be protected, and even improved.
